

# **Solid State**

# Solids

- The fixed, closely packed arrangement of particles causes a solid to have a definite shape and volume
- A **solid** is a kind of matter that has a fixed shape and a fixed volume. Your pencil is a solid. The shape and volume of your pencil will not change if you move the pencil from place to place.
- The different elements and compounds that make up matter **can be called *particles***. The particles of a solid are packed closely together.
- The ***particles*** of a solid cannot move from their spot within the solid. However, the particles can move slightly back and forth in place.

**A solid looks likes as at particle form**

# Properties of Solids

- Molecules, atoms or ions locked into a **CRYSTAL LATTICE**
- Particles are **CLOSE** together
- **STRONG INTERMOLECULAR** forces
- Highly ordered, rigid, incompressible

**Example:** ZnS (zinc sulfide)

# Properties of Solids

- **Melting point** – The crystal lattice of a solid breaks converting to a liquid
- **Enthalpy of fusion** – Energy needed to convert one mole from Solid → Liquid
  - It increases with increasing Molecular weight due to strength of Intermolecular forces
  - It increases in ionic compounds due to increase in lattice energy (depends on size and charge)
- **Sublimation** – Conversion of a solid to a gas

# Types of Solids

<b>TYPE</b>	<b>EXAMPLE</b>	<b>FORCE</b>
<b>Ionic</b>	<b>NaCl, CaF<sub>2</sub>, ZnS</b>	<b>Ion-ion</b>
<b>Metallic</b>	<b>Na, Fe</b>	<b>Metallic</b>
<b>Molecular</b>	<b>Ice, I<sub>2</sub></b>	<b>Dipole</b> <b>Ind. dipole</b>
<b>Network</b>	<b>Diamond</b> <b>Graphite</b>	<b>Extended</b> <b>covalent</b>

## Types of Solids

Type	Built from	Examples
Amorphous	Covalently bonded network with limited ordering	Glass, plastics, polymers
Ionic	+ and – ions	NaCl, CsCl, $(\text{NH}_4)_2\text{SO}_4$
Metallic	Atoms or metallic ions in sea of $e^-$	
Molecular	Molecules with internal covalent bonds, and intramolecular attractions: dipole-dipole, H-bond, London dispersion	$\text{H}_2$ , ice, $\text{I}_2$ , $\text{CH}_3\text{OH}$
Network	Atoms held in network covalent bonds	Graphite, diamond, quartz

## ➤ **Ionic crystals**

The ionic crystals consist of positively and negatively charged ions arranged in a regular fashion throughout the crystal.

## ➤ **Covalent or Network crystals**

In covalent crystals, the constituent particles are atoms of the same or different kind, which are bonded to one another by a network of covalent bonds.

## ➤ **Metallic crystals**

In metallic crystals the constituent particles are positive metal ions (kernels) i.e., nuclei where inner electrons are dispersed in a sea of mobile valence electrons.

# Metallic and Ionic Solids

# Simple Ionic Compounds

**Lattices of many simple ionic solids are built by taking a SC or FCC lattice of ions of one type and placing ions of opposite charge in the holes in the lattice.**

**Example:** CsCl has a SC lattice of  $\text{Cs}^+$  ions with  $\text{Cl}^-$  in the center.

# Simple Ionic Compounds

**CsCl has a SC lattice of  $\text{Cs}^+$  ions with  $\text{Cl}^-$  in the center.**

**1 unit cell has 1  $\text{Cl}^-$  ion plus**

**(8 corners)( $1/8 \text{ Cs}^+$  per corner)**

**= 1 net  $\text{Cs}^+$  ion.**

# Simple Ionic Compounds

**Salts with formula  
MX can have SC  
structure — but not  
salts with formula  
 $\text{MX}_2$  or  $\text{M}_2\text{X}$**

# Simple Ionic Compounds

Many common salts have FCC arrangements of anions with cations in **OCTAHEDRAL HOLES** —

**e.g., salts such as  $\text{CA} = \text{NaCl}$**

- FCC lattice of anions  $\rightarrow 4 \text{ A}^-/\text{unit cell}$
- $\text{C}^+$  in octahedral holes  $\rightarrow 1 \text{ C}^+$  at center  
+ [12 edges •  $1/4 \text{ C}^+$  per edge]  
=  $4 \text{ C}^+$  per unit cell

# Construction of NaCl

**We begin with a cube of  $\text{Cl}^-$  ions. Add more  $\text{Cl}^-$  ions in the cube faces, and then add  $\text{Na}^+$  ion in the octahedral holes.**

# The Sodium Chloride Lattice

FCC of Cl<sup>-</sup>

13m13an1.mov

**Na<sup>+</sup> ions are in  
OCTAHEDRAL  
holes in a face-  
centered cubic  
lattice of Cl<sup>-</sup> ions.**

# SODIUM CHLORIDE

FCC lattice of  
 $\text{Cl}^-$  ions

$\text{Na}^+$  ions in  
octahedral  
holes

# Comparing NaCl and CsCl

- Even though their formulas have one cation and one anion, the lattices of CsCl and NaCl are different.
- The different lattices arise from the fact that a  $\text{Cs}^+$  ion is much larger than a  $\text{Na}^+$  ion.

# Common Ionic Solids

**Titanium  
dioxide,  $\text{TiO}_2$**

**There are 2 net  
 $\text{Ti}^{4+}$  ions and 4  
net  $\text{O}^{2-}$  ions per  
unit cell.**

# Common Ionic Solids

- Zinc sulfide, ZnS
- The S<sup>2-</sup> ions are in **TETRAHEDRAL** holes in the Zn<sup>2+</sup> FCC lattice.
- This gives 4 net Zn<sup>2+</sup> ions and 4 net S<sup>2-</sup> ions.

# Common Ionic Solids

- **Fluorite or  $\text{CaF}_2$**
- **FCC lattice of  $\text{Ca}^{2+}$  ions**
- **This gives 4 net  $\text{Ca}^{2+}$  ions.**
- **$\text{F}^-$  ions in all 8 tetrahedral holes.**
- **This gives 8 net  $\text{F}^-$  ions.**

# Summary Ionic Solids

- **Compounds with formula MX are commonly either sc or fcc**
- **Many salts have NaCl structure (fcc) especially alkali metals**
- **Exceptions are CsCl, CsBr, CsI, alkaline oxides and sulfides, and oxides of 4<sup>th</sup> row transition metals (MO)**
- **Formulas can always be found from unit cell structure**

**Thanks...**
